Lab 15: Isolation and Identification of Staphylococci

**DISCUSSION**

Staphylococci ([see Fig. 6](#)) are often found in the human nasal cavity (and on other mucous membranes) as well as on the skin. They are **Gram-positive cocci** 0.5-1.0 µm in diameter and occur singly, in pairs, in short chains, and most commonly, in *irregular grape-like clusters*. The staphylococci are strongly catalase positive and generally tolerate relatively high concentrations of sodium chloride (7.5-10%). This ability is often employed in preparing media selective for staphylococci.

Staphylococcal **capsules** play a major role in the ability of the bacteria to **adhere to and colonize biomaterials**.

- **Scanning electron micrograph Staphylococcus aureus**; courtesy of Dennis Kunkel's Microscopy.
- **Scanning electron micrograph of methicillin-resistant Staphylococcus aureus (MRSA)**; courtesy of CDC
- **Scanning electron micrograph of methicillin-resistant Staphylococcus aureus (MRSA) destroying an immune cell**; courtesy of Frank Deleo, NIAID

There are five species of staphylococci **commonly associated with clinical infections**: *Staphylococcus aureus*, *S. epidermidis*, *S. haemolyticus*, *S. hominis* and *S. saprophyticus*.

**A. Staphylococcus aureus** (coagulase-positive staphylococci)

*Staphylococcus aureus* is the most pathogenic species and is implicated in a variety of infections. *S. aureus* is with some frequency found as normal human flora in the anterior nares (nostrils). It can also be found in the throat, axillae, and the inguinal and perineal areas. Approximately 30% of adults and most children are healthy periodic **nasopharyngeal carriers** of *S. aureus*. Around 15% of healthy adults are persistent nasopharyngeal carriers. The colonization rates among health care workers, patients on dialysis, and people with diabetes are higher than in the...
In the majority of *S. aureus* infections the **source of the organism** is either:

- a **healthy nasal carrier**, or
- **contact with an abscess** from an infected individual.

**The portal of entry is usually the skin.** *S. aureus* causes pus-filled inflammatory lesions known as **abscesses**. Depending on the location and extent of tissue involvement, the abscess may be called:

1. **a pustule**
   A pustule is an **infected hair follicle** where the base of the hair follicle appears red and raised with an accumulation of pus just under the epidermis. Infected hair follicles are also referred to as **folliculitis**.

2. **a furuncle or boil**
   Furuncles appear as large, **raised, pus-filled, painful nodules** having an accumulation of dead, necrotic tissue at the base. The bacteria **spread from the hair follicle to adjacent subcutaneous tissue**.

3. **a carbuncle**
   Carbuncles occur when **furuncles coalesce and spread into surrounding subcutaneous and deeper connective tissue**. Superficial skin perforates, sloughs off, and discharges pus.

*S. aureus* also causes **impetigo**, a superficial **blister-like infection of the skin** usually occurring on the face and limbs and seen mostly in young children. *S. aureus* may also cause **cellulitis**, a diffuse inflammation of connective tissue with severe inflammation of dermal and subcutaneous layers of the skin. *S. aureus* is also a **frequent cause of accidental wound and postoperative wound infections**.

Less commonly, *S. aureus* may escape from the local lesion and spread through the blood to other body areas, causing a variety of **systemic infections** that may involve every system and organ. Such systemic infections include **septicemia, septic arthritis, endocarditis, meningitis, and osteomyelitis**, as well as **abscesses in the lungs, spleen, liver, and kidneys**. *S. aureus pneumonia* may also be a secondary respiratory complication of viral infections such as measles, and influenza and is a frequent cause of nosocomial pneumonia in patients who are debilitated. Finally, *S. aureus* is frequently introduced into food by way of abscesses or the nasal cavity of food handlers. If it is allowed to grow and produces an **enterotoxin**, it can cause **staphylococcal food poisoning**.

In a 1990-1992 National Nosocomial Infections survey, CDC found *S. aureus* to be the **most common cause of nosocomial pneumonia and operative wound infections**, as well as the **second most common cause of nosocomial bloodstream infections**. Antibiotic resistant *S. aureus* is a common problem. For example, a survey conducted by CDC reported the proportion of methicillin-resistant isolates *S. aureus* (MRSA) with sensitivity only to vancomycin increased from 22.8% in 1987 to 56.2% in 1997.

Virulence factors for *S. aureus* include exotoxins such as leukocidin (kills leukocytes), alpha and delta toxins (damage tissue membranes), microcapsules (resist phagocytic engulfment and destruction), coagulase and protein A (both help resist phagocytic engulfment). Some strains also produce **TSST-1** (toxic shock syndrome toxin-1) and cause **toxic shock syndrome**, usually associated with wounds. Approximately 25% of all *S. aureus* strains are
toxigenic and approximately 6000 cases of toxic shock syndrome occur each year in the U.S. Some strains also produce exfoliatin, an exotoxin that causes scalded skin syndrome, an infection usually seen in infants and young children.

Concept map for Lab 15 - Organisms and Infections

For further information on virulence factors associated with S. aureus, see the following Learning Objects in your Lecture Guide:

- Teichoic Acids and Glycopeptides Cell Wall Fragments; Unit 3, Section C1c
- The Ability to Adhere to Host Cells: Pili and Adhesins; Unit 3, Section B2
- The Ability to Resist Phagocytic Engulfment; Unit 3, Section B5b
- The Ability to Resist Phagocytic Destruction and Serum Lysis; Unit 3, Section B5c
- The Ability to Evade Adaptive Immune Defenses; Unit 3, Section B6
- The Ability to Produce Harmful Superantigens; Unit 3, Section C2a1
- A-B Toxins; Unit 3, Section C2b
- Toxins that Damage Cell Membranes; Unit 3, Section C2c

Since most S. aureus strains produce the enzyme coagulase (see the coagulase test described below), they are often referred to as coagulase-positive staphylococci.

- Scanning electron micrograph of Staphylococcus aureus forming a biofilm in an indwelling catheter.
- Diseases and Organisms in Healthcare Settings; from CDC

B. Coagulase-Negative Staphylococci

Clinically common species of staphylococci other than S. aureus are often referred to as coagulase-negative staphylococci. These staphylococci are normal flora of the skin and, as such, frequently act as opportunistic pathogens, especially in the compromised host. S. saprophyticus is a relatively common cause of urinary tract infections, especially in healthy young women, but is seldom isolated from other sources. The great majority of infections caused by other coagulase-negative staphylococci, including S. epidermidis, S. haemolyticus, and S. hominis, are associated with intravascular devices (prosthetic heart valves and intra-arterial or intravenous lines) and shunts. Also quite common are infections of prosthetic joints, wound infections, osteomyelitis associated with foreign bodies, and endocarditis.

- Electron micrograph of Staphylococcus epidermidis colonizing a vascular catheter.

- Diseases and Organisms in Healthcare Settings; from CDC

Although certain reactions may vary from strain to strain, a series of biochemical tests will usually differentiate the most common clinically encountered species of staphylococci. Today we will use a number of tests to determine if an unknown is S. aureus, S. epidermidis, or S. saprophyticus.
**ISOLATION AND IDENTIFICATION OF STAPHYLOCOCCI**

1. **Blood agar with a novobiocin (NB) disc**

   To isolate staphylococci, clinical specimens are usually grown on Blood agar (described in Lab 14). Staphylococci produce round, raised, opaque colonies 1-2mm in diameter. The novobiocin disc is used to detect sensitivity or resistance to the antibiotic novobiocin.

<table>

<td>Sensitive</td>
<td>Sensitive</td>
<td>Resistant</td>
</tr>
</tbody>
</table>

(*) see Lab 14 for descriptions of hemolysis
(1) some strains do not show hemolysis and/or pigment
(2) some strains do show hemolysis and/or pigment
sensitive = zone of inhibition around disc
resistant = no zone of inhibition around disc

2. **Gram stain**

   All staphylococci appear as Gram-positive cocci, usually in irregular, often grape-like clusters (see Fig. 6).

3. **Mannitol fermentation on Mannitol Salt agar (MSA)**

   Staphylococci are able to tolerate the high salt concentration found in Mannitol Salt agar and thus grow readily. If mannitol is fermented, the acid produced turns the phenol red pH indicator from red (alkaline) to yellow (acid).
<table>
<thead>
<tr>
<th>Mannitol fermentation</th>
<th><em>aureus</em></th>
<th><em>epidermidis</em></th>
<th><em>saprophyticus</em></th>
</tr>
</thead>
<tbody>
<tr>
<td>Positive</td>
<td>Negative</td>
<td>Usually positive</td>
<td></td>
</tr>
</tbody>
</table>

positive = acid end products turn the phenol red pH indicator from red to yellow  
negative = prenol red remains red

4. Production of deoxyribonuclease (DNase) on DNase agar

DNase agar contains 0.2% DNA. To detect DNase production, the plate is inoculated and incubated. After growth, the plate is flooded with 1N hydrochloric acid (HCl). DNase positive cultures show a distinct clear zone around the streak (see Fig. 1) where the DNA in the agar was broken down by the bacterial DNase. DNase negative cultures appear cloudy around the growth where the acid caused the DNA in the agar to precipitate out of solution.

<table>
<thead>
<tr>
<th>Test</th>
<th><em>Staphylococcus aureus</em></th>
<th><em>Staphylococcus epidermidis</em></th>
<th><em>Staphylococcus saprophyticus</em></th>
</tr>
</thead>
<tbody>
<tr>
<td>DNase production</td>
<td>Positive</td>
<td>Negative</td>
<td>Negative</td>
</tr>
</tbody>
</table>

positive = clear zone around growth after adding 1N HCl (no DNA remaining in the agar)  
negative = cloudy around growth after adding 1N HCl (DNA remains in the agar forming a precipitate)

5. Production of coagulase

The staphylococcal enzyme coagulase will cause inoculated citrated rabbit plasma to gel or coagulate. The coagulase converts soluble fibrinogen in the plasma into insoluble fibrin.

<table>
<thead>
<tr>
<th>Test</th>
<th><em>Staphylococcus aureus</em></th>
<th><em>Staphylococcus epidermidis</em></th>
<th><em>Staphylococcus saprophyticus</em></th>
</tr>
</thead>
<tbody>
<tr>
<td>Coagulase production</td>
<td>Positive</td>
<td>Negative</td>
<td>Negative</td>
</tr>
</tbody>
</table>

positive = plasma will gel or coagulate  
negative = plasma will not gel

6. The Staphyloslide® Latex Test for cell-bound coagulase (clumping factor) and/or Protein A

The Staphyloslide® Latex Test is an agglutination test that detects cell-bound coagulase (clumping factor) and/or Protein A. Approximately 97% of human strains of *S. aureus* possess both bound coagulase and extracellular coagulase. Approximately 95% of human strains of *S. aureus* possess Protein A on their cell surface (see Fig. 7). This test uses blue latex particles coated with human fibrinogen and the human antibody IgG. Mixing of the latex reagent with colonies of the suspected *S. aureus* having coagulase and/or Protein A bound to their surface causes
agglutination of the latex particles.

<table>
<thead>
<tr>
<th>Test</th>
<th><em>Staphylococcus aureus</em></th>
<th><em>Staphylococcus epidermidis</em></th>
<th><em>Staphylococcus saprophyticus</em></th>
</tr>
</thead>
<tbody>
<tr>
<td>Cell-bound coagulase (clumping factor) and/or Protein A</td>
<td>Positive</td>
<td>Negative</td>
<td>Negative</td>
</tr>
</tbody>
</table>

positive = clumping of latex particles
negative = no clumping of latex particles

For further information on coagulase and Protein A associated with *S. aureus*, see the following Learning Objects in your Lecture Guide:

- The Ability to Resist Phagocytic Engulfment; Unit 3, Section B5b
- The Ability to Evade Adaptive Immune Defenses; Unit 3, Section B6

Staphylococci are also being identified using chemiluminescent labelled DNA probes complementary to species-specific bacterial ribosomal RNA (rRNA) sequences as well as by other direct DNA techniques.

**SCENARIO FOR TODAY’S LAB**

Choose either unknown #1 or unknown #2 as your unknown for this Case Study.

A 57 year old female who is diabetic, a smoker, and who 30 days ago had hip replacement surgery presents with pain and signs of inflammation at the surgical site. Examination shows she has a fever of 101 °F and an increased total white blood cell count with a left shift. Radiologic examination shows a deep pelvic abscess. A culture of the implant site was taken.

Assume that unknown you are given is the culture from this patient.

**MATERIALS**

1 plate of blood agar, 1 novobiocin (NB) disc, 1 plate of mannitol salt agar, 1 DNase agar plate, 1 tube of citrated rabbit plasma (coagulase test), materials to perform a Gram stain, inoculating loop

**PROCEDURE** (to be done in groups of 3)

[Keep in mind that in a real clinical situation other lab tests and cultures for bacteria other than those upon which this lab is based would also be done.]

**CAUTION: TREAT EACH UNKNOWN AS A PATHOGEN!** Inform your instructor of any spills or accidents. **WASH AND SANITIZE YOUR HANDS WELL** before leaving the lab.
1. Do a Gram stain on the unknown (see Lab 6). Make sure you review the instructions before you do the Gram stain.

   Instructions for the Gram Stain from Lab 6.

   Instructions for Focusing a Microscope from Lab 1.

2. Using your loop, streak your unknown for isolation on a plate of Blood agar as described below.

   a. Using a sterile inoculating loop, streak your unknown for isolation on a blood agar plate so as to get single, isolated colonies (Fig. 2, step 1, Fig. 2, step 2, and Fig. 2, step 3). Before you streak your plate draw an "X" on the bottom of the blood agar plate to indicate where you begin the streaking pattern.

   b. Using your inoculating loop, stab the agar several times in each of the growth areas in order to detect oxygen-sensitive hemolysins (Fig. 2, step 4).

   c. Place a novobiocin antibiotic disc in the center of the area of the plate that you streaked first (the area where you drew the "X") where you expect to see heaviest growth (Fig. 2, step 5).

   d. Incubate upside down and stacked in the petri plate holder on the shelf of the 37°C incubator corresponding to your lab section until the next lab period.

3. Streak your unknown for isolation on a plate of Mannitol Salt agar (MSA) as shown in Fig. 3. Incubate upside down and stacked in the petri plate holder on the shelf of the 37°C incubator corresponding to your lab section until the next lab period.

   Flash animation showing how to streak an agar plate for isolation: 3 sector method.

   html5 version of animation for iPad showing how to streak an agar plate for isolation: 3 sector method.

4. Streak a single line of your unknown down the center of a plate of DNase agar as shown in Fig. 4. Incubate upside down and stacked in the petri plate holder on the shelf of the 37°C incubator corresponding to your lab section until the next lab period.

5. Inoculate a tube of citrated rabbit plasma with your unknown and incubate your test tube rack at 37°C.

RESULTS
Case Study Lab Report for Lab 15:
Staphylococci

The concept behind the case studies presented in Lab 15 used to illustrate the genus *Staphylococcus* is for you and your lab partners as a group to:

1. Come up with a valid diagnosis of the type of infectious disease seen in your case study and identify the bacterium causing that infection.

2. Support your group’s diagnose based on:
   a. Any relevant facts in the patient’s history. (A reliable on-line source will be used to support this.)
   b. The patient’s signs and symptoms. (A reliable on-line source will be used to support this.)
   c. Each of the individual lab tests given in your case study.
   d. All microbiological lab tests you performed as part of the project.

The due date for this report can be found on the class calendar. Remember, you are working as a group to solve a problem. Your grade for this lab is based on the completeness of your report and written evidence of the critical thinking process that went into making and supporting your diagnosis. Therefore, it is critical that all members of the group participate, question any conclusions being made by the group, and contribute to the report. Remember, you are trying to convince your instructor that you understand how the diagnosis was made by supporting that diagnosis with data. Your group will work together to write the report and submit one hard copy of that report for your group. Part of your grade will be based on evaluation of your work by your team members.

Be sure to handle all the bacterial cultures you are using in lab today as if they are pathogens! Be sure to wash and sanitize your hands well at the completion of today’s lab.

Also, make sure you observe the results of someone in your lab who had an unknown different from yours. The Performance Objectives for Lab 15 tell you what you are expected to be able to do on the practical.

Each member of the group must:

1. Print a copy of each of the two rubrics from the links above.
2. Print and fill out a copy of the Team Member Evaluation Form from the link above.
3. Staple them together and hand them in to me the day your Lab 15 Case Study Lab Report is due.
A 57 year old female who is diabetic, a smoker, and who 30 days ago had hip replacement surgery presents with pain and signs of inflammation at the surgical site. Examination shows she has a fever of 101 °F and an increased total white blood cell count with a left shift. Radiologic examination shows a deep pelvic abscess. A culture of the implant site was taken.

1. Patient's history and predisposing factors

Read the case study. Explain how any relevant parts of the patient’s history contributed to your diagnosis as to the type of infectious disease seen here. You are urged to use the computers in lab to search reliable medically oriented Internet sources to support this. Reliable sources you might consider are Medscape (http://emedicine.medscape.com/infectious_diseases) and The Centers for Disease Control and Prevention (CDC) at http://www.cdc.gov/. Cite any sources you use at the end of this Patient’s History section in APA style (http://www.apastyle.org/).

The patient's history should suggest a general type of infectious disease that is present, such as a urinary tract infection, a wound infection, gastroenteritis, pharyngitis, pneumonia, septicemia, etc. Do not look up the bacterium you eventually identify as the cause of this infectious disease. You don't know the causative bacterium at this point. You need to determine the general type of infection in order to determine what microbiological tests to perform to identify the bacterium causing the infection. Search at least one medically-oriented reference article from a reliable site such as Medscape and use this article to support your diagnosis of the type of infectious disease seen here. Don't forget to cite any sources you used in APA style.
style directly under this Patient's History and Patient's Symptoms sections of this Lab Report.

2. Patient's signs and symptoms

Read the case study. Explain how the patient’s signs and symptoms contributed to your diagnosis as to the type of infectious disease seen here. You are urged to use the computers in lab to search reliable medically oriented Internet sources to support this. Reliable sources you might consider are Medscape (http://emedicine.medscape.com/infectious_diseases) and The Centers for Disease Control and Prevention (CDC) at http://www.cdc.gov. Cite any sources you use at the end of this Patient's Symptoms section in APA style (http://www.apastyle.org/).

The patient's signs and symptoms should suggest a general type of infectious disease that is present, such as a urinary tract infection, a wound infection, gastroenteritis, pharyngitis, pneumonia, septicemia, etc. Do not look up the bacterium you eventually identify as the cause of this infectious disease. You don’t know the causative bacterium at this point. You need to determine the general type of infection in order to determine what microbiological tests to perform to identify the bacterium causing the infection. Search at least one medically-oriented reference article from a reliable site such as Medscape and use this article to support your diagnosis of the type of infectious disease seen here. Don’t forget to cite any sources you used in APA style directly under this Patient's History and Patient's Symptoms sections of this Lab Report.

3. Results of laboratory test given in the case study

List each lab test given and explain how the results of that test helps to contribute to your diagnosis. The CBC test is described in Appendix C of this lab manual.

4. Microbiological lab tests you performed in Lab 15

a. Gram stain

Give the Gram reaction (Gram-positive or Gram negative and how you reached this conclusion) and the shape and arrangement of the unknown you were given. State how this contributed to your decision as to which microbiological tests and/or media to use next. The Gram stain is discussed in Lab 6.

b. Blood agar with novobiocin (NB) disc

Give the results of the Blood agar with Taxo NB disc you performed on the unknown you were given, and how you reached this conclusion. State how this contributed to your your decision as to what bacterium is causing the infection. The possible results for Blood agar and NB disc were discussed in the beginning pages of this lab.

c. Mannitol Salt agar

Give the results of the Mannitol Salt agar you performed on the unknown you were given, and how you reached this conclusion. State how this contributed to your your decision as to what bacterium is causing the infection. The possible results for Mannitol Salt agar were discussed in the beginning pages of this lab.
d. DNase agar

Flood the surface of your DNase agar plate with 1N HCl. Give the results of the DNase agar you performed on the unknown you were given, and how you reached this conclusion. **State how this contributed to your decision as to what bacterium is causing the infection.** The possible results for DNase agar were discussed in the beginning pages of this lab.

e. Coagulase test

Give the results of the Coagulase test you performed on the unknown you were given, and how you reached this conclusion. **State how this contributed to your decision as to what bacterium is causing the infection.** The possible results for the Coagulase test were discussed in the beginning pages of this lab.

**Final Diagnosis**

Infection: ________________________________

PERFORMANCE OBJECTIVES FOR LAB 15

After completing this lab, the student will be able to perform the following objectives:

DISCUSSION

1. Name three common clinically important species of Staphylococcus and state which species is most pathogenic.

2. State the sources and the portal of entry for most Staphylococcus aureus infections.

3. Name and describe three types of abscesses caused by Staphylococcus aureus.

4. Name four systemic Staphylococcus aureus infections.

5. State the significance of Staphylococcus aureus enterotoxin, the exotoxin TSST-1, and the exotoxin exfoliatin.

6. Name the infection normally caused by Staphylococcus saprophyticus.

7. Name the types of infections most commonly caused by coagulase-negative staphylococci other than Staphylococcus saprophyticus.

ISOLATION AND IDENTIFICATION OF STAPHYLOCOCCI
1. State the Gram reaction and morphology of all staphylococci.

2. Describe the typical reactions of *S. aureus*, *S. epidermidis*, and *S. saprophyticus* on each of the following media:

   a. Blood agar (pigment, hemolysis, novobiocin resistance)
   b. Mannitol Salt agar (for mannitol fermentation)
   c. DNase agar (for the enzyme DNase)
   d. coagulase test with citrated rabbit plasma
   e. Staphyloslide® test for bound coagulase and/or Protein A

RESULTS

2. Recognize an organism as *Staphylococcus aureus* and state the reasons why after seeing the results of the following:

   a. a Blood agar plate with a novobiocin disc
   b. a Mannitol Salt agar plate
   c. a DNase agar plate
   d. a tube of citrated rabbit plasma
   e. a Staphyloslide® test
